ELI v2.0 — The Complete Setup Guide (Plain English)

> **Updated for v2.1.51 (August 2026).** The primary way to install ELI is now the **prebuilt installers on GitHub Releases** — `ELI-Setup-<v>.exe` (Windows), the `.dmg` (macOS, Apple Silicon), the `.AppImage` (Linux). The Linux AppImage and Windows installer are built and launch-tested in CI; the macOS `.dmg` is built on a Mac and provided best-effort (not verified in CI). First launch offers GPU acceleration (NVIDIA CUDA / AMD Vulkan; Apple Metal is built in) and a starter model sized to your hardware. Data lives in a per-user `ELI_v2` folder and survives upgrades; `--fresh-start` resets it. Everything below remains valid for **source installs** (clone + `install.sh`) and the classic portable tarball.

Everything you need to install, set up, and run ELI — written for a person, not a programmer. If you can copy and paste, you can do this.

What you're about to install

ELI is an AI assistant that lives **entirely on your own computer**. There's no account to create, no subscription, and nothing you say to it ever leaves your machine unless you deliberately ask for something from the internet (like the news or a model download).

You install it once, download a "brain" (an AI model file) once, and after that it works completely offline.

What you need before starting:

Requirement	Details
A computer	Linux is the best-tested. Windows and macOS installers exist too.
Python 3.10 or newer	Most modern Linux systems already have it. Check with `python3 --version`
Disk space	~2 GB for ELI itself, plus 2–5 GB for a model (more if you pick a big one)
A GPU (graphics card)	**Optional but recommended.** NVIDIA is best supported. Without one, ELI still works — just slower.
Internet	Only for the install itself and the one-time model download.

Part 1 — Getting ELI onto your computer

The easy way (recommended): download a release package

1. Go to the releases page: **https://github.com/ShadowESC95/ELI_v2.0/releases**
2. Download the newest Linux portable file — it looks like: `ELI_v2-<version>-linux-portable.tar.gz`
3. Open a terminal in your Downloads folder and run:

```
tar -xzf ELI_v2-*-linux-portable.tar.gz
cd ELI_v2-*-linux-portable
chmod +x ELI_Setup.sh
./ELI_Setup.sh
```

`ELI_Setup.sh` is the guided, "just press Enter" path — it walks through every step below automatically and opens the setup wizard at the end. **If you used this, you can skip straight to Part 3.**

There's also an AppImage (`ELI_v2-*-x86_64.AppImage`) — make it executable (`chmod +x`), double-click it, done.

The developer way: from the source code

```
git clone https://github.com/ShadowESC95/ELI_v2.0.git
cd ELI_v2.0
bash install.sh
```

That one command does all of this for you:

1. **Looks at your computer** — CPU, RAM, disk space, and what GPU you have (NVIDIA, AMD, Apple, or none).
2. **Shows you a plan** — what it's going to install and why — and asks permission before touching anything.
3. **Creates a private workspace** (a "virtual environment" in a `.venv` folder) so it never interferes with the rest of your system.
4. **Installs the AI engine** built for *your* hardware — CUDA build for NVIDIA, ROCm for AMD, Metal for Mac, or a plain CPU build.
5. **Verifies the GPU actually works** — and warns you loudly if you ended up with the slow CPU version by accident.
6. **Installs the helper tools** ELI uses to control your desktop — media playback, screenshots, clipboard, OCR (screen reading), microphone support.
7. **Offers to download a model** sized to your graphics card.
8. **Fetches the small required extras** — the memory "embedder" (~85 MB, needed for ELI's long-term memory) and the voice files (speech-to-text + a speaking voice).

9. **Sets up fresh, empty databases** — ELI starts knowing nothing about you.

Installer options (only if you want them)

You can add these to the end of `bash install.sh`:

Flag	What it means in plain English
`--yes`	"Don't ask me questions, just use the sensible defaults."
`--cpu-only`	"Ignore my GPU, run on the processor." (slower, but always works)
`--install-cuda`	"I have an NVIDIA card but no CUDA toolkit — install that for me too."
`--model=qwen2.5-7b`	"Download this specific model while you're at it."
`--auto-model`	"Pick the best model for my hardware and download it."
`--no-model`	"Don't download anything big — I'll add a model myself later."
`--latest`	"Use the newest versions of everything instead of the tested, frozen set."
`--skip-torch`	"Skip PyTorch." (saves space; disables self-training features)

Example — completely hands-off install with an automatic model:

```
bash install.sh --yes --auto-model
```

Windows

Double-click **`install.bat`** — it launches the full PowerShell installer, which does the same job as the Linux one (CUDA install, dependency lock, GPU verification, database setup). Options:

```
install.bat            (normal – NVIDIA CUDA install)
install.bat /cpu       (no GPU / force CPU)
install.bat /cuda      (also install the CUDA toolkit if missing)
```

Then launch with **`eli.bat`**.

macOS

Same as Linux — `bash install.sh`. It automatically uses Apple's Metal GPU acceleration. The first time ELI takes a screenshot or moves your mouse, macOS will ask you to allow Screen Recording and Accessibility in System Settings → Privacy — grant them and retry.

Part 2 — Giving ELI a brain (the model)

ELI needs a model file (a `.gguf` file) to think with. If you didn't grab one during install, you have three easy options:

Option A — let ELI pick for you (measures your graphics card, picks what fits):

```
.venv/bin/python -m eli.core.model_download --auto
```

Option B — see the menu and choose yourself:

```
.venv/bin/python -m eli.core.model_download --list      # see what's on offer
.venv/bin/python -m eli.core.model_download --choose    # pick any number of them
```

Model	Size	What you need	Who it's for
Qwen2.5-3B	~1.8 GB	4 GB GPU or CPU	Older machines, laptops
Qwen2.5-7B *(default)*	~4.4 GB	8 GB GPU	The sweet spot for most people
Qwen3-8B	~4.7 GB	8 GB GPU	Adds deeper reasoning
Falcon3-10B	~5.9 GB	12 GB GPU	Stronger answers
Phi-4 (14B)	~8.4 GB	12 GB GPU	High quality, MIT licensed
Qwen3.6-35B-A3B	~20.6 GB	24 GB GPU / big CPU	Enthusiast tier
Falcon-H1-34B	~18.9 GB	24 GB GPU / big CPU	Enthusiast tier

Option C — bring your own. Download any chat/instruct `.gguf` file from the internet (Hugging Face is the usual place) and drop it into the `models/` folder. ELI finds it automatically and adapts itself to fit it into whatever memory you have. It is not locked to any brand of model.

The starter pack: the release page also has a tag called `local-assets-v2.1` containing a small starter model, the memory embedder, and voice files. If you have the GitHub `gh` tool set up, `./RUN_ELI.sh --with-github-assets` (portable package) fetches it all in one go.

Part 3 — Starting ELI

The desktop app (the main event)

```
./scripts/eli_launch.sh
```

or simply:

```
./eli.sh
```

The **first launch shows a setup wizard**: it asks what to call you, lets you pick your model and voice, and explains the network toggle. ELI starts as a blank slate — it knows nothing about you until you talk to it.

After install you'll also have **"ELI v2.0" in your app menu** (the installer adds desktop icons on Linux), so you can start it with a click like any other program.

Talking to it

Type in the chat box, or speak — say the wake word (you can set your own; train it in Settings) and just talk. Ask it *"what can you do?"* and it will list everything — all 208 of its capabilities, generated from what's genuinely wired in.

The phone / tablet view (optional)

ELI has a built-in web page you can open from any device **on your own home network**. The AI still runs on your computer — your phone is just a window onto it.

```
./scripts/eli_serve.sh          # just this computer → http://127.0.0.1:8081/
./scripts/eli_serve.sh --lan    # whole home network → prints a protected link + QR code
```

With `--lan` it automatically creates an access token and prints the exact address to type into your phone's browser. Never expose this to the open internet — it's for your home Wi-Fi only.

You can also run both at once (server in the background, desktop app in front):

```
./scripts/eli_launch.sh both --lan
```

Terminal-only mode (no windows)

```
.venv/bin/python -m eli --headless
```

Commands inside it: `/status`, `/mode`, `/reset`, `/help`, `/quit`.

Part 4 — The commands cheat-sheet

Everything in one place. Run these from the ELI folder.

Install & repair

```
bash install.sh                    # full install (asks first)
bash install.sh --yes --auto-model  # fully automatic install + model
./scripts/eli_setup.sh             # guided 8-step first-time setup (the gentle path)
```

Launch

```
./scripts/eli_launch.sh            # desktop app
./scripts/eli_launch.sh serve --lan # web app for phone/tablet
./scripts/eli_launch.sh both --lan  # both at once
./eli.sh                           # desktop app (shortcut)
.venv/bin/python -m eli --headless  # text-only terminal mode
```

Models

```
.venv/bin/python -m eli.core.model_download --list     # what can I download?
.venv/bin/python -m eli.core.model_download --auto     # pick one for my hardware
.venv/bin/python -m eli.core.model_download --choose   # let me pick from a menu
.venv/bin/python -m eli.core.model_download --aux      # just the memory embedder
```

Voice files (if they didn't download during install)

```
.venv/bin/python -m eli.runtime.voice_assets
```

Health checks

```
bash run_tests.sh                  # run the test suite
bash eli_diagnose.sh               # system diagnosis report
```

Part 5 — Understanding the privacy switches

These are the promises the software makes, in plain terms:

- **Offline by default.** ELI blocks its own network access at a deep level (the socket layer). When it's offline, its own code *cannot* dial out even if it tries. You flip network access on with one toggle — and ELI announces when it goes online.
- **Your data stays put.** Conversations, your profile, memories — all in local database files inside the ELI folder (`artifacts/`). Delete them any time; ELI simply starts fresh.
- **No account, no telemetry.** Nothing phones home. There's nothing to phone home *to*.
- **One honest caveat:** ELI can run commands and read files on your computer — that's its job as an assistant. Its safety rails are good but not a prison; treat it like a capable tool you're in charge of, not a sandboxed toy. The details live in `SECURITY.md`.

Part 6 — When something goes wrong

Symptom	The fix
"Python 3.10+ required"	Install Python from python.org (Windows) or your package manager (`sudo apt install python3`).
ELI is painfully slow	Your AI engine is probably running on CPU. Re-run `bash install.sh --install-cuda` (NVIDIA). The installer tells you at the end whether GPU offload is on.
`.venv not found — run install.sh first`	You skipped the install, or you're in the wrong folder. `cd` into the ELI folder and run `bash install.sh`.
No sound / voice doesn't work	Run `.venv/bin/python -m eli.runtime.voice_assets`, and make sure `ffmpeg` and `portaudio` installed (the installer prints the exact command if it couldn't do it itself).
First reply after launch is slow	Normal — the model loads into memory on first use. A big model can take a minute.
Out-of-memory / crashes mid-answer	Your model is too big for your GPU/RAM. Download a smaller one (`--auto` picks a safe size).
Phone can't reach the web app	Use `--lan`, make sure both devices are on the same Wi-Fi, and check your firewall allows port 8081.
macOS won't screenshot / move mouse	System Settings → Privacy & Security → grant Screen Recording + Accessibility, then retry.
Wrong model loaded	Settings tab → pick a different model, or drop a new `.gguf` into `models/`.

Still stuck? Open an issue with what you saw: **https://github.com/ShadowESC95/ELI_v2.0/issues** — a plain "I tried it and this happened" is genuinely useful.

Part 7 — Removing ELI

ELI never spreads itself around your system. To remove it completely:

```
rm -rf /path/to/ELI_v2.0        # the folder is the whole install
```

That's it — models, databases, settings, everything lives inside that one folder. (If you added the app-menu icons, remove them with your desktop's app editor or delete the `.desktop` files from `~/.local/share/applications/`.)
